Getting Started with iSiLK

Introduction

iSiLK is a graphical front-end for the SiLK tools, designed to work with an existing installation of the SiLK flow analysis suite. The application uses the SSH protocol to connect to an analysis server, issue commands and copy data files. This manual assumes you're already using iSiLK with a standard SSH application, and that you'll be configuring iSiLK to use the same settings.

iSiLK provides an easy-to-use alternative interface to the core functionality of the SiLK tool suite that makes it easier for an analyst to organize his analysis work, interactively explore analysis results, and share those results with other analysts.

It's important that you have a basic understanding of the SiLK tools and how to apply them before using iSiLK. Although it's possible to begin using iSiLK immediately for simple queries, to get the most value from the tool, it's recommended that you first familiarize yourself with the SiLK tools and the basics of flow analysis before getting started.

iSiLK is currently available for Microsoft Windows XP and Vista, and as Python source that can be run on most Unix systems, and on Mac OSX. This manual describes using the binary distribution of the application for Windows. For information about running iSiLK on other platforms, consult the Development and Deployment Guide.

New Features in iSiLK 0.1.5

A variety of new features and bug fixes are included in iSiLK 0.1.5, including:

- Allowing a user to cancel a query or a download
- An rwstats tool
- Improved problem set management, including support for deletion
- Bug fixes to remote import
- Bug fixes associated with quitting & saving while jobs are running
- Bug fixes associated with picking set and prefix maps
- Eliminated assumptions of file type based on file extension
- Improved error messages and other usability improvements
- More robust handling of ssh errors

Installation

This manual assumes that you or your system administrator has already set up a flow collection system and that you have secure shell (SSH) access to a system with the SiLK tools installed. If that's not the case, before you can use iSiLK you'll need to install SiLK and configure it to collect and store flow data collected on your network. The SiLK tools can be downloaded from:

<http://tools.netsa.cert.org/>

where you'll find a variety of other information about SiLK, flow analysis and other related tools.

iSiLK is distributed as a Windows installer with the extension “.msi”. You can simply double click on this file to install iSiLK under Program Files on your system and add iSiLK to your Start menu. For information about running iSiLK on other platforms, or directly from the command line using an existing installation of Python, consult the Development and Deployment Guide.

Configuring iSiLK

Unless your system administrator has already configured iSiLK for you, the first time you run iSiLK you'll be prompted to configure your default SSH settings. This will allow iSiLK to connect to an analysis server with the SiLK tools.

Before launching iSiLK for the first time, make sure you know the following:

- The host name or remote IP address of the analysis server where the SiLK tools are installed.
- Your user id on that server.

You'll also need a valid SSH key pair, installed on your desktop machine and the server to allow communication between iSiLK and the remote host.

Creating an SSH Key Pair

Unless your system administrator has already configured your iSiLK set up, you will need to make sure you have a valid SSH key pair. You can use an existing keypair or you can run generate the keys on the remote system.

Assuming that the remote server is running openssh on the analysis server, you'll need to use `ssh-keygen` on the server to produce a new key pair and install the public key on the server in your authorized keys file (generally found in your `.ssh` directory under your home directory). The process will be similar for other SSH implementations. The private key should reside on the windows machine in a location where iSiLK will be able to read the file.

After logging into the remote system you'll need to run `ssh-keygen` on the analysis system—or another Unix system—to generate keys. You will be prompted for the file in which to save the key. For example, if you enter “id_isilk”, the exchange will look like:

```
remotehost$ ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/home/jdoe/.ssh/id_rsa): id_isilk
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in id_isilk.
Your public key has been saved in id_isilk.pub.
The key fingerprint is:
5e:9a:02:40:f6:25:58:fd:f4:17:24:22:56:9b:ff:f4
```

This will create two key files, `id_isilk` and `id_isilk.pub`, your private and public key, respectively. In order to use this key to log into this analysis host, you'll need to append the contents of the public key file to your ssh authorized keys file:

```
remotehost$ cat mynewisilkkey.pub >> ~/.ssh/authorizedkeys
```

The next step is to move the private key (`id_isilk`) to your desktop machine. Generally you'll do this using a secure copy application running on your desktop. ("scp"). For security reasons, you should copy the private key to a directory that only you can read.

Testing your SSH Connection

Before running iSiLK for the first time you may want to make sure you can invoke SiLK tools using a standard command-line ssh client if you have one installed. This will allow you verify that SiLK is installed properly, that your PATH is properly set, and that the SSH setup is correct. For example, run:

```
C:\> sshclient.exe -i id_mykey me@host rwfilter -help
```

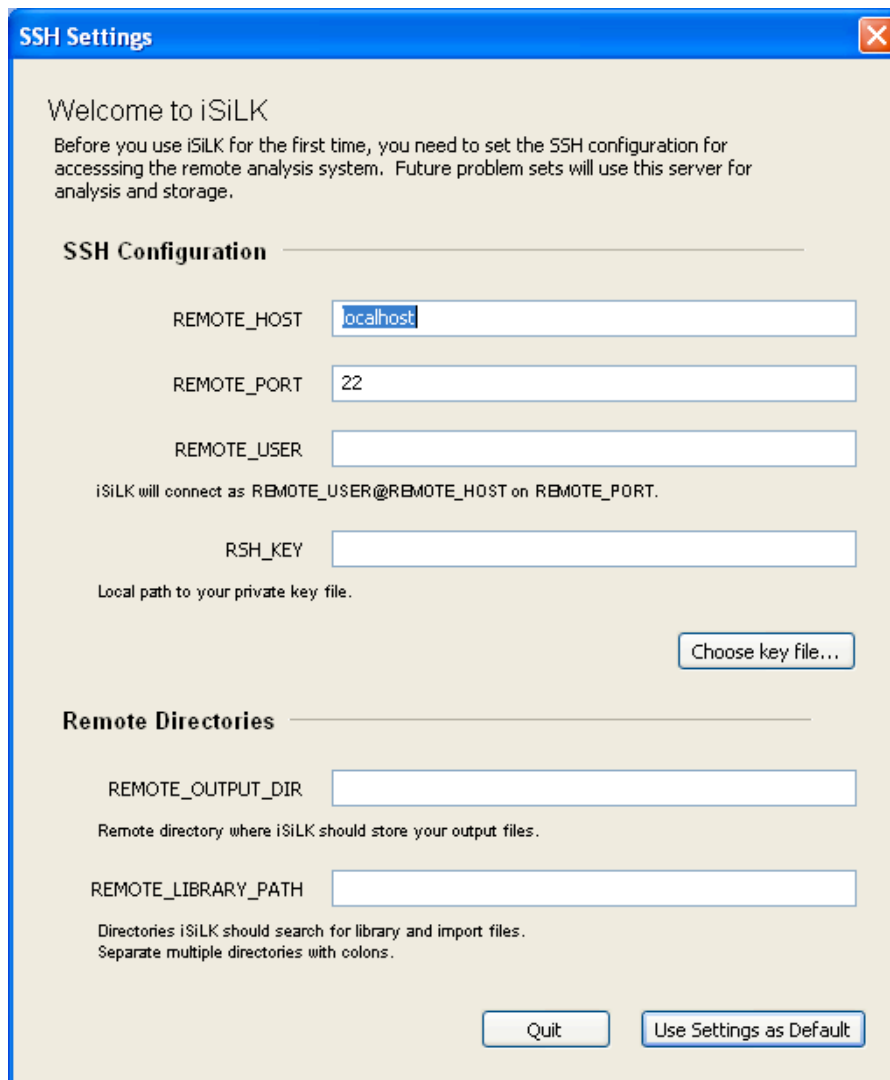

If you don't have a command line ssh client installed on the machine running iSiLK, you can log into the server and ssh back into it:

```
$ ssh -i id_mykey localhost rwfilter -help
```

You can then verify `rwfilter` runs and that its output is the same as you see when you log with an ssh console application and run that command directly at the Unix command prompt.

Editing the iSiLK Configuration Settings

When you run iSiLK for the first time, you will be given the opportunity to set the default iSiLK configuration to match the setup, keys, and remote host and login information that is unique to your SiLK configuration.

The image shows a 'SSH Settings' dialog box with a blue title bar and a close button. The main area is light beige. It starts with a 'Welcome to iSiLK' message and a paragraph explaining the need for SSH configuration. Below this is a section titled 'SSH Configuration' with a horizontal line. It contains four text input fields: 'REMOTE_HOST' (pre-filled with 'localhost'), 'REMOTE_PORT' (pre-filled with '22'), 'REMOTE_USER' (empty), and 'RSH_KEY' (empty). Below the 'RSH_KEY' field is a small text label 'Local path to your private key file.' and a 'Choose key file...' button. The next section is 'Remote Directories' with a horizontal line. It contains two text input fields: 'REMOTE_OUTPUT_DIR' and 'REMOTE_LIBRARY_PATH'. Below 'REMOTE_OUTPUT_DIR' is a small text label 'Remote directory where iSiLK should store your output files.' and below 'REMOTE_LIBRARY_PATH' is a small text label 'Directories iSiLK should search for library and import files. Separate multiple directories with colons.' At the bottom right are two buttons: 'Quit' and 'Use Settings as Default'.

SSH Settings

Welcome to iSiLK

Before you use iSiLK for the first time, you need to set the SSH configuration for accessing the remote analysis system. Future problem sets will use this server for analysis and storage.

SSH Configuration

REMOTE_HOST

REMOTE_PORT

REMOTE_USER

iSiLK will connect as REMOTE_USER@REMOTE_HOST on REMOTE_PORT.

RSH_KEY

Local path to your private key file.

Remote Directories

REMOTE_OUTPUT_DIR

Remote directory where iSiLK should store your output files.

REMOTE_LIBRARY_PATH

Directories iSiLK should search for library and import files.
Separate multiple directories with colons.

All of the fields displayed in this dialog box are required by iSiLK.

- The REMOTE_HOST field should correspond to the IP address or host name of the server on which you normally run the SiLK tools.
- The REMOTE_USER field should contain your user name on this machine.
- The REMOTE_PORT is the ssh port to connect on the remote machine. Generally, you'll just leave this to its default value of 22, the standard port for SSH.
- The RSH_KEY is the full path name of the file on your machine (e.g., C:\id_isilk).

You'll also need to tell iSiLK about the directories where you'll store analysis results:

- The `REMOTE_OUTPUT_DIR` field should refer to the directory where you normally store output files. This may correspond to your home directory or a separate output directory (e.g., `/output/jdoe/isilk`).
- The `REMOTE_LIBRARY_PATH` is a set of directories separated by a colon (":") where iSiLK should look for sets and other secondary data files. This is also the directory that iSiLK will search for remote files to import.

When you click “Configure Defaults”, iSiLK will test these settings by issuing a series of simple commands. If iSiLK is unable to connect to the server it will display an error message to help you understand the issue.

One common error that may be displayed is “`rwfilter: command not found`”. This indicates that your `PATH` is not set properly. You’ll need to be sure that the SiLK binary installation directory is included in your path. Typically this means adding a line to a shell configuration file on the server (e.g., “`.bashrc`” if your Unix shell is `bash`) that looks like:

```
PATH=$PATH:<PREFIX>/bin
```

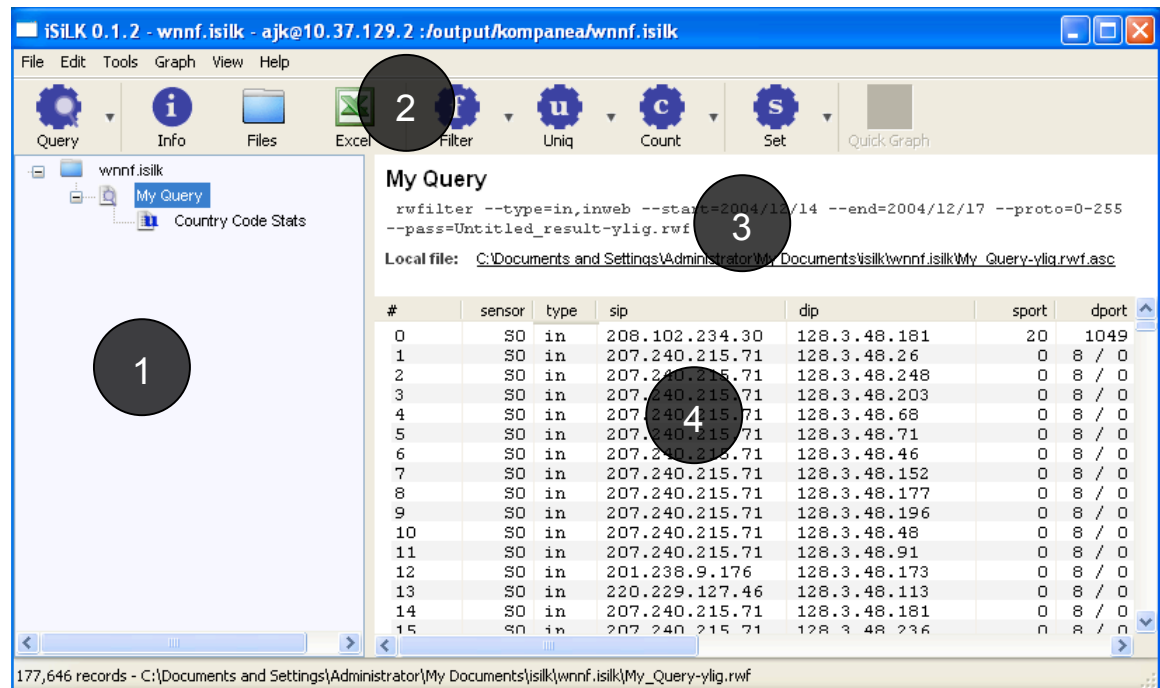

Where `<PREFIX>` is where the SiLK tools are installed. Typically this is “`/usr/local`”.

Once you successfully configure iSiLK, you can begin using the tool.

A Brief Tour of iSiLK

iSiLK is designed around the concept of a “problem set”, a collection of related flow data, analysis results and graphs.

When iSiLK starts you will be given an opportunity to open an existing problem set or open a new problem set. The problem set will be displayed within a new Problem Set Explorer window:

There are four major components of a Problem Set Explorer:

1. The **Result Tree**, which will contain the results of any analyses you run. When you create a new problem set this tree will be empty.
2. The **Toolbar**, which includes buttons for each of the tools available within iSiLK (also available through the Menu). The arrow on the right side of each button will bring up a menu from which plug-ins can be selected, if any are configured for that tool (see the Plug-in section below for more information).
3. An **Information Panel** that displays basic information about the current result (more details may be displayed by selecting the Info button).
4. A **Result View** that displays a record-oriented or graphical view of the analysis result selected in the Result Tree.

Typically, your first step will be a “data pull” –an `rwfilter` query—to investigate some network activity of interest. For example, a typical query would be for all flows in the last day associated with a particular source IP address. This will be

followed by subsequent filtering of the data, analysis and related queries. As you run further analysis on the data, these results are appended to the analysis Result Tree. You can browse to any result by selecting it in the tree. Every result is displayed under the parent data set that was used as input to the analysis. iSiLK currently provides interfaces to the following SiLK tools:

- `rwfilter` for queries (the Query Builder tool)
- `rwfilter` for “drilling down” on query results (the Filter tool)
- `rwcount` for time-series counting
- `rwuniq` for other counting
- `rwset` for creating sets

It’s important to note that the analysis tools are always run on the remote analysis system, *not* locally. Every result is stored remotely until you explicitly choose to download it for browsing by clicking on the remote path displayed in the Information Panel at the top of the result.

Querying the Repository with the Query Builder

Tools → Query → Query Builder provides a simplified interface for users for querying the flow data repository.

Query Builder (hwjj.isilk)

Basic Query Options | More Filter Options

Data files to search
Data Pool (class/type): Border - Incoming

`rwfilter --type=in,inweb --start-date=2008/11/14:15 --proto=0-255 --pass=$output`

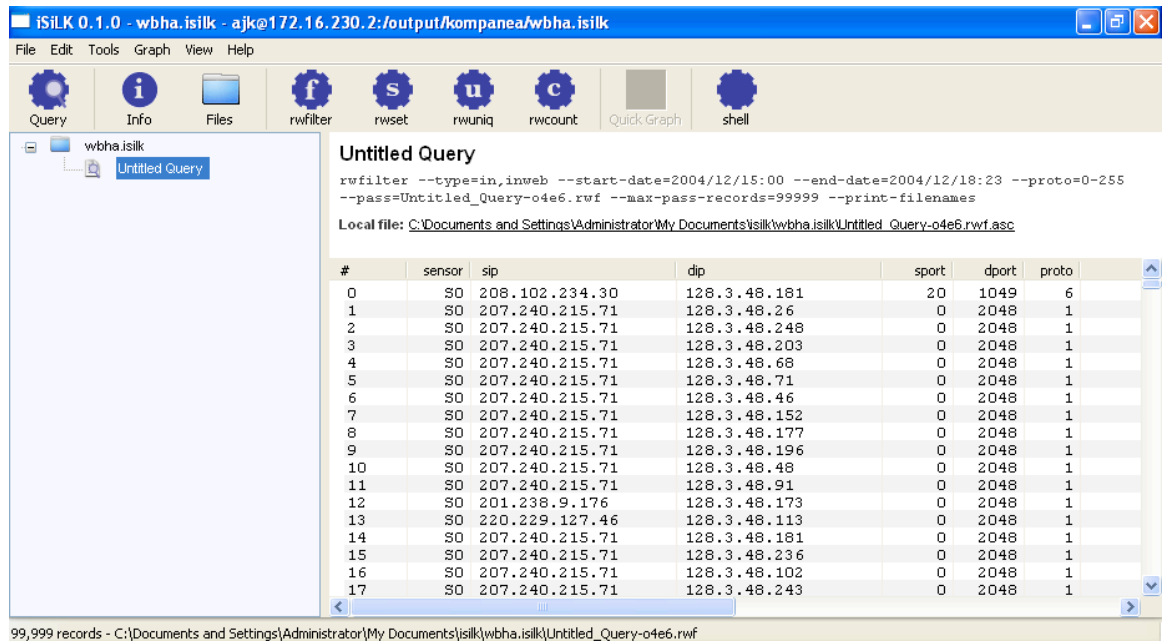

Name: Untitled Query Add to: hwjj.isilk ☐ Return records that FAIL filter

Close Validate Options Run Remote Query

Using the Query Builder you can:

- Easily select query options including the time period to search and the source and destination of traffic.
- Select from common rfilter options by selecting “More Filter Options”. Using the additional filter options you can filter based on protocol-specific fields (i.e., ICMP type and code and TCP flags), traffic volumes and using a prefix map.
- Display the rfilter command-line equivalent for the currently selected query.
- Select from common options, and site-specific defaults.

The result of the query will be added to the Result Tree. When the query completes, the result of the query will be available on the remote machine. In order to browse the result, you will need to download the result by clicking on the path to the remote file displayed in the Information Panel. After doing that you’ll be presented with a view that looks something like the following:

Using the record browser displayed in Result View you can:

- Browse the records returned by the query by using the standard list controls.
- Sort records by clicking on the appropriate column header.
- Select records to copy to the clipboard by selecting “Copy as tabular data” from the Edit menu (e.g., to paste into Excel)

Filtering based on the Selection

You can formulate additional queries and filter further based on the current selection in the record browser displayed in the Result View. After selecting a record of interest, you can:

- Query the repository based on the record by right clicking and selecting the appropriate item from the pop up menu. This will add a new query result to the Result Tree.
- Filter the results further by double-clicking (to select all records associated with the given sip, dip, sport, dport and proto), right clicking and selecting an item from the pop up menu, or using **Tools → Filter → *rwfilter...***

In the second case, you'll have an opportunity specify additional filtering criteria. This will add a new "Filter Result" underneath the result that you've drilled down on:

Validate Options Cancel Run Analysis

Using the rwuniq Tool to Summarize Traffic

Tools → Uniq → rwuniq... provides a subset of the options provided by the SiLK `rwuniq` command line tool. Using `rwuniq` you can:

- Specify one or more fields to count by (the key fields)
- Select a prefix map to use for counting based on symbolic labels.
- Specify one or more totals to calculate from among bytes, packets, flow records, unique source IPs and unique destination IPs.
- View the corresponding `rwuniq` command line.

The result will be displayed in a record browser in the Result View. The following shows bytes and packets totals based on protocol:

Graphing rwuniq Results

iSiLK has a simple graphing capability available through the **Graph → Quick Graph** tool. After selecting an `rwuniq` result in the Result Tree, click on the **Quick Graph** tool to display a simple bar graph:

You can display a popup tooltip with more details about a bar in the graph by moving the mouse over the bar. You can also drill down on the data corresponding to a particular bar by double clicking on it.

Using the Count Tool for Time-Series Counting

Tools → Count → rwncount... provides a simplified interface to the rwncount command-line tool. Using rwncount you can:

- Specify a time bin size.
- View the corresponding rwncount command line.

Note that rwncount uses the *default* rwnuniq option for assigning totals to particular time bins.

Graphing rwcount Results

Like rwuniq results, rwcount results can be graphed using the **Quick Graph** tool:

Importing Data

File → Import Data File... allows you to select a file on the remote analysis server to import into the current problem set (e.g., the result of some scheduled analysis process). When you choose this menu option, iSiLK will search the contents of all the directories in your `REMOTE_LIBRARY_PATH` (see **Tools → SSH Settings...**) looking for files with particular file name extensions that indicate their type. You can import the following file types using the import feature:

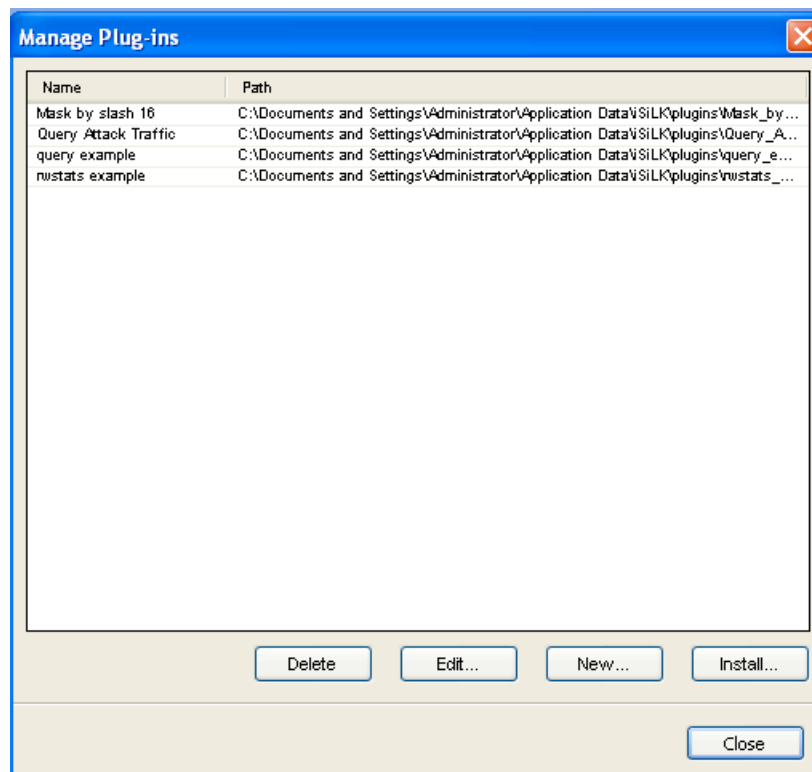

- Binary flow data file (.rwf)
- Binary set file (.set or .bin)

Creating a Plug-in Based on a Command Line

iSiLK provides a mechanism that can be used to save a commonly-used command line as a plug-in tool, the iSiLK equivalent of a “macro” or “script”. A plug-in is an arbitrary command line that generates a single output file based on an analysis of the current selection or based on a “query”. A query can consist of an actual rfilter-style query of the repository, or it can be any command that retrieves flow data (e.g., a command invocation that returns the result of some automated process).

Tools → Manage plug-ins... will display all of the currently registered plug-in tools:

To create a new plug-in based on a command-line you specify, click on “New...”. This will display a dialog that will you provide a tool name, specify the command line to use, and choose the category of tool you’re creating:

The command line template is an arbitrary Unix command line that can produce either binary flow data or columnar ASCII output that iSiLK consumes. Use the special “wildcard” string \$input to refer to the file name for the currently selected result in the problem set explorer—for a query, you can leave \$input off the command line. Similarly, use \$output where you would normally specify an output file name. One use of this feature is to make an otherwise unavailable SiLK application available from within iSiLK. For example, you can create a simple “Mask 24” tool for masking by /24, for example, to generate statistics in terms of source network using rwniq, by specifying a command line like:

```
cat $input | rwnetmask --sip-prefix=24 --output-path=$output
```

Note the use of the cat command above. This is necessary since rwnetmask is expecting to read its input from standard input rather than a file. For SiLK tools that let you specify an input file name this isn’t necessary.

After clicking on “Create plug-in”, the new tool will appear on the **Tools** menu as “Mask 24” and on the menu adjacent to the appropriate toolbar button based on the category you’ve specified.

Running an Arbitrary Unix Command Line

If the built-in set of tools doesn’t include a capability you need, but you don’t need to create a new tool you can use **Tools → Run shell command...** to execute an arbitrary command line. This tool will display a dialog very similar to the dialog used to create a command line plug-in. See the discussion above for details.

Other Features

A variety of other features are available as menu options. These include:

- **File → Show Local Files** will display the contents of the local working directory corresponding the current problem set. This includes text versions of all analysis results and graphics for files for all graphs.
- **File → Import Remote Data File...** will search your remote library path for files to import (e.g., the result of a cron job).
- **Tools → SSH Settings...** allows you to adjust the ssh settings for the current problem set as well as the default settings for future problem sets.

Use caution when changing the output directory for a non-empty problem set. iSiLK will not copy results to a new directory. It is possible to manually copy results to a new directory and then change the output directory setting, *but this is not recommended.*

- **View → Command Log** displays command line history in a panel at the bottom of the problem set.

- **View → Show File Info** displays an information box with information about the currently selected result, including the information returned by the `rwfileinfo` tool for query and filter results. Also available through the Info tool on the Toolbar.
- **View → View Options...** allows you choose which of the available columns to display in a particular record view and to select from options that affect how field values are displayed in the record view.
- The **Help** menu includes items for the commonly used SiLK tools. Selecting one of these items will launch your web browser and display the appropriate documentation page on the SiLK public release web site.

Running iSiLK from the command line

iSiLK can be launched from a Command Prompt or from another application, and includes command line options for automatically launching a query when iSiLK is started. This provides a simple way to integrate iSiLK with other applications.

A typical invocation might look something like:

```
C:\>isilk.exe --type=in,inweb --start-date=2008/01/16
--end-date=2008/01/17 --saddress=10.1.1.1
```

The above will launch iSiLK with a new empty problem set and immediately launch a query for all incoming traffic between the 15th and 17th of January in 2008 associated with the source IP address 10.1.1.1.

You can display all of the command line options available in iSiLK using the help option option:

```
C:\>isilk.exe --help
```

The following sections describe some of the command line options supported by iSiLK.

Creating a new problem set based on a query

From the command line you can a new problem set based on a query using one more of the rfilter “pass-through” command line options supported by iSiLK. These include the rfilter “selection switches” used to select which data files to search in the repository:

```
--class=CLASS
--type=TYPE
--sensors=SENSORS
--start-date=START_DATE
--end-date=END_DATE
```

as well as some of the common “partitioning switches”, including:

```
--saddress=SADDRESS
--daddress=DADDRESS
--any-address=ANY_ADDRESS
--dport=DPORT
--sport=SPORT
--aport=APORT
--proto=PROTO
```

Creating a new problem set based on imported files

You can also create a new problem set that includes copies of a set of SiLK binary data files available on the analysis server. This can be used as a simple way to import the result of a cron job running on the server, or a data file generated by running the command line tools.

Use the `--import-files` option with a comma-separated list of remote files to import as analysis results. These files should correspond to paths on the server you've configured as your default analysis host. For example:

```
C:\>isilk.exe --import-files=/shared/file1.rwf,/shared/file2.rwf
```
